RECRUITMENT & PLACEMENT MANAGEMENT SYSTEM

Java + MySQL Project Abstract

Project Abstract

The **Recruitment & Placement Management System** is a Java and MySQL based application designed to manage the complete recruitment and placement lifecycle of students or candidates in a training institute or placement organization.

The system maintains centralized information about candidates, companies, job openings, applications, eligibility criteria, interview rounds, feedback, offers, joining status, and final placements. It helps reduce dependency on spreadsheets and manual tracking by providing a structured and database-driven process.

The application is developed using **Java, Object-Oriented Programming, JDBC, Collections, Exception Handling, File Handling, and MySQL**. A layered architecture is followed using Model, DAO, Service, Utility, Exception, and Main/Application layers so that business logic and database operations remain properly separated.

The system includes an **Eligibility Engine** that verifies whether a candidate satisfies job requirements such as qualification, passing year, percentage, technology, backlog criteria, and other conditions before allowing the application to proceed.

The application manages the complete recruitment workflow: **Candidate Registration -> Eligibility Verification -> Job Application -> Shortlisting -> Interview Scheduling -> Interview Feedback -> Selection -> Offer -> Joining -> Placement.**

Important business rules such as duplicate application prevention, valid status transitions, role-based operations, transaction management, audit history, and data validation are implemented to make the project similar to a real industry application.

MySQL is used for persistent storage, relational data management, joins, reporting, and transaction handling. JDBC with PreparedStatement is used for secure database communication.

HTML and CSS pages are developed only as **UI prototypes** to represent how a future web-based version of the system may look. These prototype pages are not connected to the Java backend.

The project demonstrates practical implementation of Java concepts, JDBC, SQL, layered architecture, database design, business validations, exception handling, reporting, and real-world recruitment workflows.

Project Type: Industry-oriented backend business application with HTML/CSS UI prototype.
